1. Introduction

1.1 Background

Background

In June 2017, Barwon Water acknowledged that the historic management of groundwater pumping activities had led to a reduction in groundwater contribution from the Lower Tertiary Aquifer into Boundary Creek, a tributary of the Barwon River. This reduction, in conjunction with changes in land use, Millennium Drought, and the complexities associated with management and regulation of a private on-stream dam that controls flows into the lower reaches of Boundary Creek, resulted in the increased frequency and duration of 'cease to flow' and 'acid flush' events along Boundary Creek and Big Swamp – a wetland that is primary fed by inflows from Boundary Creek. This was despite meeting the provisions set out in the ground-water extraction licence(s) that were intended to offset the potential impacts from Barwon Water's groundwater pumping activities on Boundary Creek.

In May 2018, Barwon Water established the community and stakeholder Remediation Working Group to participate in the design and development of a remediation plan for Boundary Creek and Big Swamp. As part of this process, Barwon Water invited the working group to nominate their own technical experts to help support them in their discussions to shape the remediation plan.

In September 2018, Barwon Water's commitment to undertake remedial works was legally strengthened through the issuing of a Ministerial Notice under section 78 of the Water Act, 1989. This notice mandated the development and implementation of the Boundary Creek, Big Swamp and Surrounding Environment – Remediation and Environmental Protection Plan (REPP), which was subsequently approved by Southern Rural Water in February 2020. The objectives of the REPP are twofold:

1. The Boundary Creek and Big Swamp Remediation Plan - That outlines the controls and actions that have and will be implemented within the confirmed areas of impact to:
 - a. Ensure no further harm from Barwon Water's remediation actions
 - b. Protect the water quality and ecological values of the Barwon River
 - c. Improve the water quality and streamflows within Boundary Creek, and
 - d. Improve the ecological values of Big Swamp.
2. The Surrounding Environment Investigation - To investigate whether other areas within the regional groundwater system have been impacted by historical management of groundwater extraction activities at the Barwon Downs borefield.

The selection and assessment of these controls and actions has been guided by an adaptive management approach, which has been conducted in accordance with the endorsed governance framework, involving significant engagement with Southern Rural Water and community and stakeholder groups.

Once all of the success targets outlined in this REPP have been met and any further actions required as part of the surrounding environment investigation are complete, remediation is deemed to have been

completed to the extent practicable, thus, meeting the requirements of the section 78 notice and the cessation of the REPP.

This report has presents the results of the vegetation monitoring conducted within the swamp from 2020 until 2023. The purpose of the result is to determine if an 'improvement in the ecological values with Big Swamp' has, and continues to, occur.

1.2 Success criteria

To inform the preparation of the Boundary Creek and Big Swamp Remediation Plan, a set of interim success criteria were developed to assess 'improvement of ecological values in Big Swamp'. These success criteria were based on ecological conditions within the swamp prior to the millennial drought, and the subsequent fires and associated disturbance which has fundamentally modified the swamps environment and associated ecological values. The success criteria were:

- No further encroachment of terrestrial woodland into the swamp plain.
- No encroachment of Lowland Forest dominant species into areas of Damp Forest.
- No loss of structural or floristic diversity along the main channel and western end of the swamp.
- Increase diversity of understorey species within the swamp plain, with a focus on ferns and sedges.

Subsequent review of the factors which lead to degradation of the swamp from the late 1990s to early 2010s, including those outside of Barwon Waters control such as droughts and modification of surface flows upstream and downstream of Big Swamp, have prompted review of these success criteria. In particular, remediation is not intended to return the swamp to pre-drought conditions, recognising the significant changes that have occurred and the need to facilitate the swamps natural recovery to ensure the establishment of a functional, resilient ecosystem. Based on this evaluation, alternative success criteria are being developed which compare recovery of the swamps ecological condition and function based on post-pumping, drought, and fire events, so these can more accurately assess recovery and progress against worst case condition (circa. 2012). The success criteria will also consider realistic timeframes within which to evaluate the recovery of the swamp as a result of remedial actions undertaken by Barwon Water.

1.3 Study area

The study area covers the wetland and riparian extent of Big Swamp near Yeodene, Victoria within parcels 115A\PP3987 and 1\PS501652 (Figure 1). This 22-hectare area is defined by the hydrological influence of Boundary Creek and the associated groundwater-dependant ecosystem. Areas outside of the immediate influence of the swamp's hydrology, including those upstream/slope of the swamp and downstream of the parcels identified, are not included in the study area.

1.4 Monitoring approach

Monitoring of big swamp is being undertaken to determine how the system is responding to remedial works, and assess the nature of the swamp's recovery. To do this, monitoring is based around the assessment of the vegetation's composition, structural and floristic diversity.

The composition of vegetation within the swamp provides an indication of the communities present, based on structural and floristic characteristics. These communities can be assigned an Ecological Vegetation Class and used to determine potential long-term shifts in the nature of the swamps ecosystem.

Floristic and structural diversity is a measure of the swamps ecological health. This recognises that when disturbance is minimised, or within the bounds of what would be considered normal for the system, complexity in both the type and form of plants will increase over time.

Based on this, a monitoring program was developed that involved:

- 50-metre-long point transects established as part of the ecohydrological assessment (ELA 2019, ELA 2021).
- Flora quadrats in each of the ecohydrological zones to measure floristic diversity (ELA 2021)

1.5 Limitations

The 2022 surveys saw an influx of water into the study area, following a wet winter period. This prevented ELA from accessing several of the monitoring points. These points were surveyed at the start of 2023. This resulted in several transects being surveyed outside of the usual monitoring period. This may influence what flora species were present at the time of survey.

Additionally, the metal stakes for two monitoring points were unable to be found (Transect 8 and Quadrat 5). Both monitoring points were remeasured where the GPS points were located. The stakes were never found. This may have also resulted in a difference in the species recorded within each respective monitoring point.

2. Existing environment

The ecology of Big Swamp is complex and intricately linked to the hydrology of the site. The hydrology is in turn informed by a range of factors including soils, topography and climate, as well as surface water flows, upstream water use and connection with the upper aquifer system. In addition to the aforementioned factors, Boundary Creek is a modified system that, until groundwater levels recover, is reliant on surface level inflows being released from the dam upstream.

From as early as the 1800s, the swamp has been affected by changing land and water use as vegetation clearance and agricultural practices expanded across the region. These activities have continued to the current day. Unfortunately, the cumulative effects have come to a head over the past 20 years with drought conditions triggering intensive ground water extractions and severely limiting surface flows into the swamp. The result was the drying of the swamp through the 1990s and 2000s. While difficult to ascertain, this drying may have commenced prior to groundwater extraction as the installation of MacDonalds Dam upstream would have changed the flow regime along Boundary Creek from the late 1970s. As the water table dropped and drying occurred, both the vegetation and underlying soil layers rich in organic carbon became susceptible to fire, with two major events occurring in 1998 and 2011. The latter fire resulted in an almost complete loss of vegetation cover across the swamp, substantially altering the structure of the communities throughout. Whilst fire was not uncommon within the local vicinity (5 kms of the swamp) (LTU 2023), the aforementioned fires were likely detrimental to the overall health of the swamp. Subsequently, it appears erosion of the swamp plain, driven by large rainfall events combined with exposed post-fire soils, has concentrated surface flows into a secondary channel that now bisects the plain. The resulting eroded sediment appears to have in part accumulated at the eastern end of the swamp in the form of a plug, leading to the formation of a pool of standing water which persists year-round.

An assessment of historical and current vegetation diversity and condition within Big Swamp completed by ELA (2019) identified three distinct ecohydrological zones within the swamp in 2019 (Figure 1). Within each zone, vegetation associations based on known community types and floristic and structural condition were identified. The zones and associations identified in 2019 formed the basis for the success criteria and associated monitoring program, and are discussed further below.

2.1 Swamp Plain

The Swamp Plain is dominated by the recently described Riparian Fern Scrub (EVC A120) vegetation community. Riparian Fern Scrub is endangered and restricted to the Otway Ranges and possibly higher rainfall areas of the Gippsland Plain (Frood unpublished). This community commonly occurs on humous-rich soils and requires near-continuous waterlogging of the soil with shallow, often prolonged, periods of inundation. Where conditions result in frequent or prolonged inundation, sedges and rushes are likely to be dominant in the understorey. Alternatively, drier conditions would see a shift to a fern dominated understorey with emergent trees common.

The majority of this community has been significantly modified by the previous fires. This resulted in the loss of much of the original understorey diversity. The most heavily affected areas are now dominated by Prickly Tea-tree (*Leptospermum continentale*) or Scented Paperbark (*Melaleuca squarrosa*) with occasional patches of Austral Bracken (*Pteridium esculentum*) and/or Red-fruit Saw-

sedge (*Gahnia sieberiana*). More intact patches occur in the far west of the swamp in areas apparently less affected by fires, supporting a diverse ground layer dominated by various sedges such as Tall Sedge (*Carex appressa*) and Tassel Sedge (*Carex fascicularis*). Areas closer to the main channel in the north of the site contained a braided system of channels and supported a higher cover of sedges and ferns, including additional species such as Spreading Rope-rush (*Empodisma minus*) and Scrambling Coral-fern (*Gleichenia microphylla*). Riparian Fern Scrub vegetation associations identified within the swamp are listed in Table 1.

Table 1. Riparian Fern Scrub vegetation associations in Big Swamp

Vegetation associations	Description	Floristic diversity	Structural diversity	Dominant species
High-diversity riparian fern scrub (RFS120-A)	A structurally and floristically complex riparian scrub exhibiting a diversity of fine-scale variation.	High	Moderate-high	Woolly Tea-tree (<i>Leptospermum lanigerum</i>), Tall Sedge (<i>Carex appressa</i>), Tassel Sedge (<i>Carex fascicularis</i>)
Dry riparian fern scrub (RFS120-B)	Dense to open scrub with a ground layer of Bracken, occasional emergent <i>Eucalyptus ovata</i> .	Low	Low-moderate	Prickly Tea-tree (<i>Leptospermum continentale</i>), Scented Paperbark (<i>Melaleuca squarrosa</i>), Austral Bracken (<i>Pteridium esculentum</i>)
Wet riparian fern scrub (RFS120-C)	Dense scrub with little or no understorey, interspersed with narrow channels supporting a low-diversity of sedges and ferns. Occasional emergent <i>Eucalyptus ovata</i> .	Low-moderate	Low-moderate	Prickly Tea-tree (<i>Leptospermum continentale</i>), Scented Paperbark (<i>Melaleuca squarrosa</i>), Red-fruit Saw-sedge (<i>Gahnia sieberiana</i>)

2.2 Woodlands

Woodlands include the treed sections of the swamp across the eastern half of the swamp, as well as Lowland Forest communities immediately bordering the swamp.

Damp woodlands occur on the lower slopes to the south and east of the main swamp, in areas that are unlikely to experience inundation in normal years.

This community was dominated by young Swamp Gum (*Eucalyptus ovata*) with a very species-poor understorey containing Austral Bracken and Red-fruit Saw-sedge. Whilst this community has been described as Damp Sands Herb-rich Woodland due to its current structural and floristic characteristics (which is likely a result of recent fires and changes in hydrology), this vegetation is considered to represent a derived state of the Swamp Gum (*Eucalyptus ovata*) Forest described by Carr and Muir (1994). This community has been identified throughout the region on the lowest slopes in association with braided streams, swampy flats and swamp margins, and is believed to have occupied the southern margin and eastern end of Big Swamp prior to ground-water extraction commencing. Damp Sands Herb-rich Woodland vegetation associations identified within the swamp are listed in Table 2.

Table 2. Damp Sands Herb-rich Woodland vegetation associations in Big Swamp

Vegetation associations	Description	Floristic diversity	Structural diversity	Dominant species
Modified, open Damp Sands Herb-rich Woodland (DSHW3-A)	A highly modified, immature woodland comprised of small stands of recruiting Swamp Gum interspersed with open, treeless areas of Austral Braken.	Low	Low	Swamp Gum (<i>Eucalyptus ovata</i>) and Austral Braken (<i>Pteridium esculentum</i>)
Modified, closed Damp Sands Herb-rich Woodland (DSHW3-b)	A modified, dense woodland of recruiting Swamp Gum. While generally supporting a limited understorey, small pockets of diversity were observed throughout.	Low-moderate	Low-moderate	Swamp Gum (<i>Eucalyptus ovata</i>), Austral Braken (<i>Pteridium esculentum</i>) and Prickly Moses (<i>Acacia verticillata</i>)

Lowland Forest (EVC 16) occurs on the slopes surrounding Big Swamp, upslope from Damp Sands Herb-rich Woodland, in areas unaffected by water-logging or inundation. This floristically diverse community is dominated by Messmate Stringybark (*Eucalyptus obliqua*) and Manna Gum with a high cover of Austral Bracken. Prominent shrubs included Silver Banksia (*Banksia marginata*), Prickly Moses (*Acacia verticillata*) and Sweet Bursaria (*Bursaria spinosa*). Lowland Forest vegetation associations identified adjacent to the swamp are listed in Table 3.

Table 3: Lowland Forest vegetation association within Big Swamp

Vegetation association	Description	Floristic diversity	Structural diversity	Dominant species
Lowland Forest (LF16-A1)	A diverse woodland with varied canopy cover dominating the drained, eastern-most edge of the swamp. Likely colonised the area due to draining of the swamp downstream.	High	High	Brooker's Gum (<i>Eucalyptus brookeriana</i>), Hazel Pomaderris (<i>Pomaderris aspera</i>), Soft Tree-fern (<i>Dicksonia antarctica</i>)

2.3 Main Channel

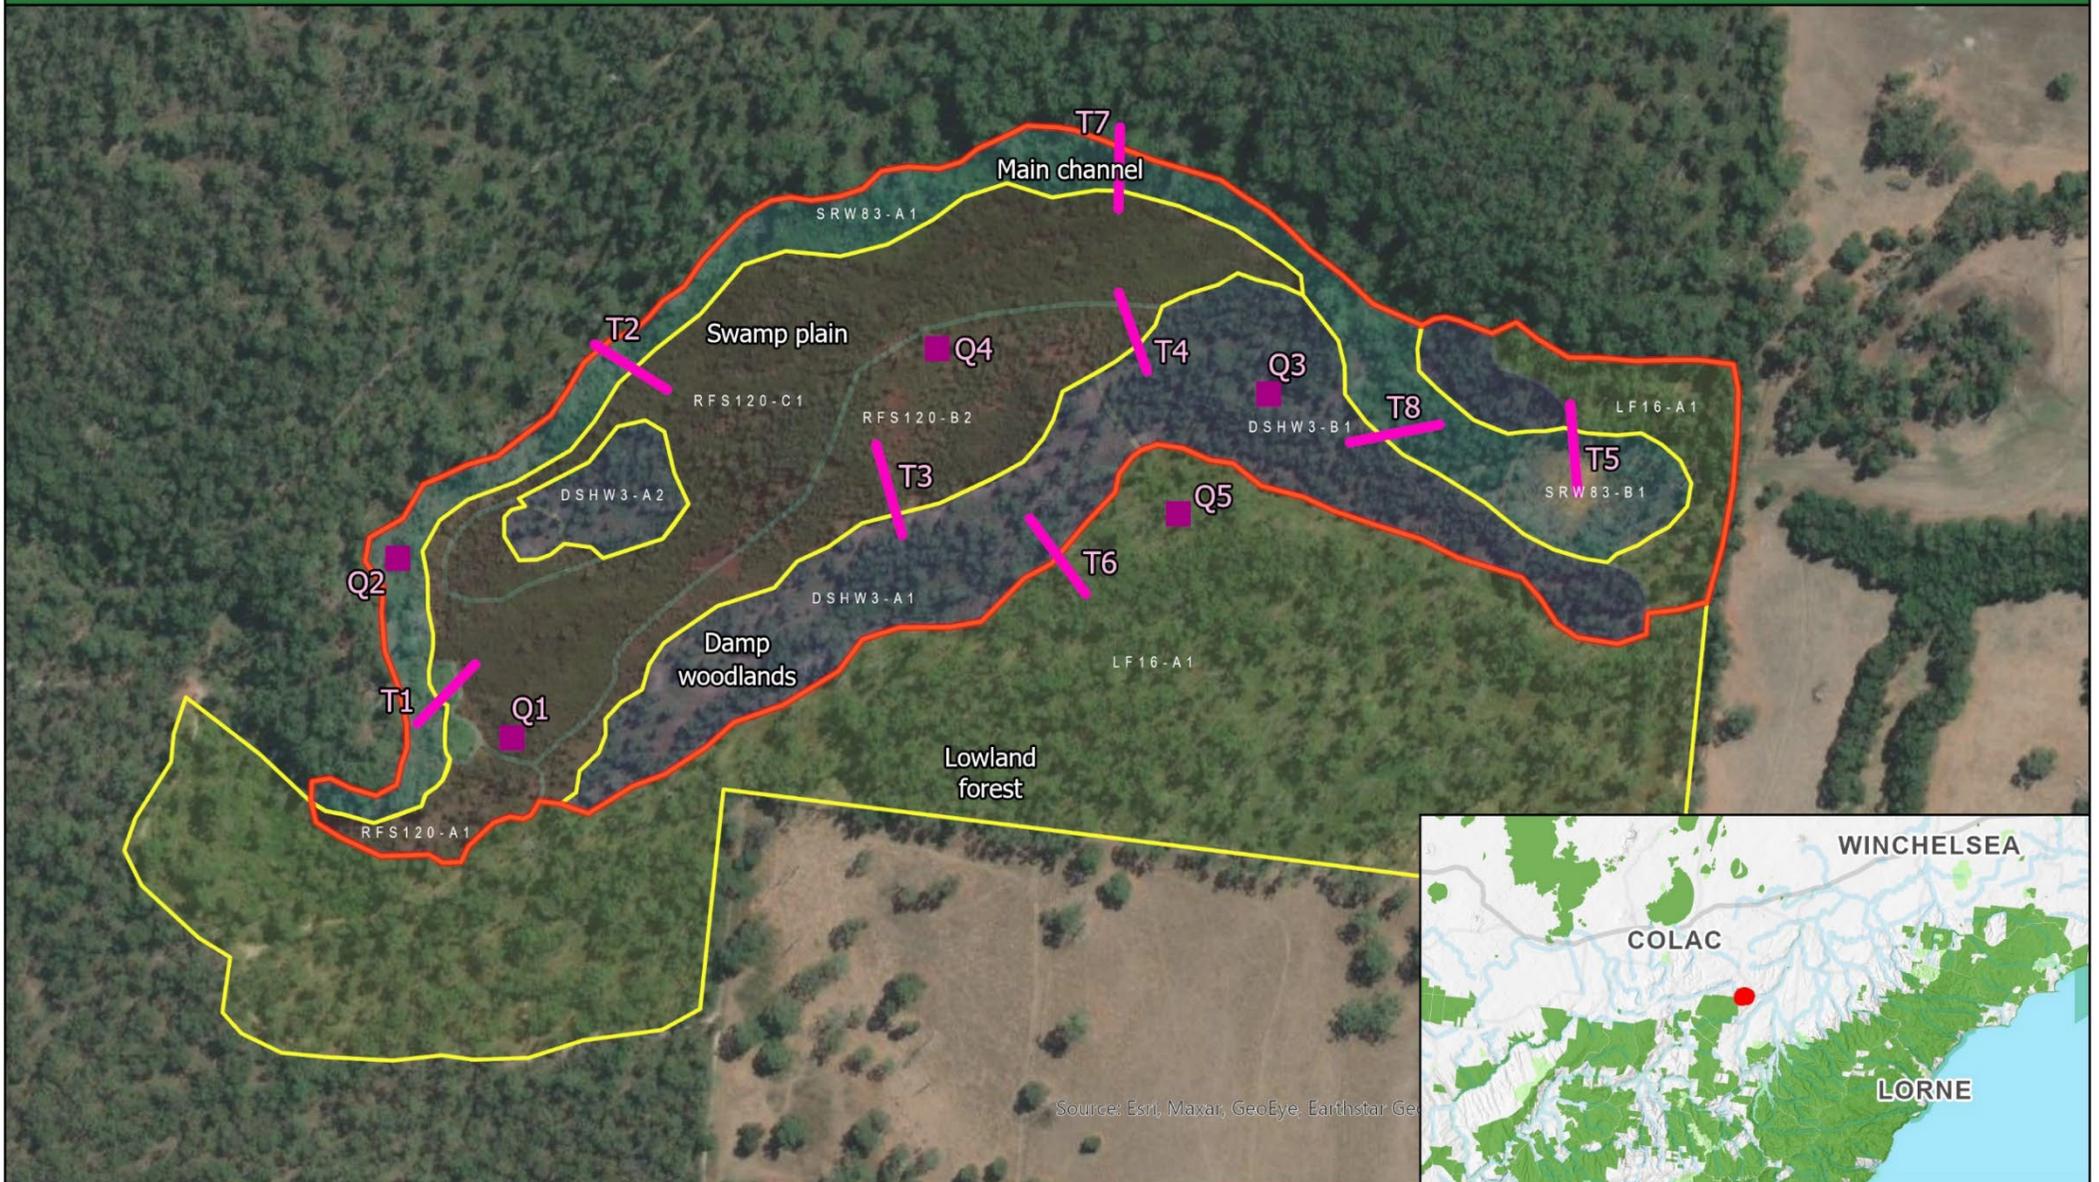

The Main Channel is located along the northern edge of the swamp, and is associated with the Swampy Riparian Woodland community which is reliant on surface flows along the main channel and associated infiltration into the surrounding ground layer. The depth of the channel and variation in elevation along the banks means inundation may have been limited to seasonal floods and localised depressions. Tall forest species less tolerant of inundation, such as Brooker's Gum and Manna Gum, were also present further up the bank as the community shifted into Lowland Forest on the northern edge.

Swampy Riparian Woodland contains a scattered tree layer, dominated by Swamp Gum (*Eucalyptus ovata*), Brooker's Gum (*Eucalyptus brookeriana*) and Manna Gum (*Eucalyptus viminalis*), often over a secondary tree layer. In elevated sections with limited inundation a variety of ground, scrambling and tree ferns were common. The creek channel supported a range of aquatic and semi-aquatic forbs and

sedges. Swampy Riparian Woodland vegetation associations identified within the swamp are listed in Table 4.

Table 4. Swampy Riparian Woodland vegetation associations in Big Swamp

Vegetation associations	Description	Floristic diversity	Structural diversity	Dominant species
High-diversity Swampy Riparian Woodland (SRW83-A)	Following the main channel, this structurally and floristically complex riparian woodland exhibits a diversity of fine-scale variation.	High	High	Swamp Gum (<i>Eucalyptus ovata</i>), Brooker's Gum (<i>Eucalyptus brookeriana</i>), Woolly Tea-tree (<i>Leptospermum lanigerum</i>), Hazel Pomaderris (<i>Pomaderris aspera</i>), Common Water-ribbons (<i>Cycnogeton procerum</i>), Soft Tree-fern (<i>Dicksonia antarctica</i>)
Flooded Swampy Riparian Woodland (SRW83-B)	A flooded section of woodland with only dead stags persisting. Wetland and aquatic vegetation has begun to colonise shallow sections.	Low	Low	N/A

3. Methods

The vegetation assessments were conducted by ELA ecologists Griffin Taylor-Dalton, James Garden and Elise Keane from 16 to 18 November 2022 and the 1 February 2023. Methods for each of the survey tasks are described below.

3.1 Vegetation transects

The vegetation of the study area was sampled using eight 50m long vegetation transects aligned from the perimeter of the swamp into the core, crossing various vegetation community boundaries in the process (Table 5). The start of each transect was permanently marked with a 1500mm high, yellow-capped star picket so that the transects can be used for ongoing monitoring. A photo point was established at the star picket at the start of each transect.

The location of transects were chosen so as to intersect vegetation association boundaries which are considered to align with environmental gradients or features (e.g. inundation, soils etc). This will allow for the future comparison of floristic diversity and structure associated with the differing vegetation associations (and therefore underlying environmental drivers), whilst also providing the basis for tracking gradual changes in the extent of vegetation communities over the long-term.

All flora species at each 25cm interval along the transect were recorded. In addition, the ground attribute occurring at each 25cm point was recorded, including one of either bare ground, bryophytes, litter, water and log. The data provides an overall frequency of each plant species and ground attribute occurring across the transect as well as a snapshot of the distribution of functional plant groups and species across wetland gradients. Transect data has been used to inform the dominant species associated with each vegetation association.

3.1.1 Analysis

The 50 m transects within Big Swamp include the transition point between two vegetation types. The transition point is the key point for monitoring, as it will determine over time whether the vegetation communities in the swamp are encroaching, receding, or transitioning.

Results of species records from each of the 200 monitoring points along the transects in the Big Swamp were converted into a vegetation dominance code, to analyse the overall environment of the transects. Species lists from each of the vegetation types identified in the report Assessment of historical and current vegetation diversity and condition within Big Swamp (ELA 2019) were used to develop a list of key and indicator species, then each point along the transect was compared to this list and coded for dominance of vegetation type. The code choice was manually assigned by an ecologist based first on overstorey, then on the dominant characters of the understorey. When no vegetation was present, or the site contained only weeds, the groundcover recorded was reported (i.e. litter, bryophytes, logs and water). The transect data were randomised to prevent any perceived patterns biasing the ecologists code choice.

The vegetation types and dominant species are given in Appendix A.

Table 5. Transect locations and vegetation types

3.2 Flora species quadrats

Five flora species quadrats were assessed within the Big Swamp and surrounding vegetation (Table 6). The dimensions of each quadrat were 8 x 8 metres. A full floristics survey was completed within each quadrat. Native species were assigned a cover/abundance value using the Braun-Blanquet scale (Table 7) and then allocated lifeforms based on the following:

- Trees
- Large and medium shrubs (>1m)
- Small and prostrate shrubs (<1m)
- Herbs
- Grasses
- Ferns
- Epiphytes
- Scrambler/climbers
- Sedge/rushes

3.2.1 Analysis

Results from the quadrats were analysed for floristic (species) diversity as well as structural diversity. The following paragraphs describe the two different types of analysis employed for this study.

Floristic diversity

Floristic diversity was measured by calculating the sum of the total number of species present within each quadrat.

Structural diversity

Structural diversity was calculated using the Simpsons Index of Diversity (Magurran 2004). The Simpsons Index of diversity measures the probability of selecting two individuals at random that belong to the same lifeform. As the value produced by this index is a probability, the value must range from 0 – 1. By applying the index, a 0 represents no diversity whereas a 1 represents high amounts of diversity.

To calculate the index, the following equation must first be calculated:

$$D_s = \sum n_i(n_i - 1) / N(N - 1)$$

Where:

n_i = total number of organisms of a given species

N = total number of organisms of all species

The result of this equation is then subtracted from 1 to obtain Simpsons Index of Diversity:

$$1 - D_s = \text{Simpsons Index of Diversity}$$

The Braun-Blanquet cover abundance was used as a proxy for the total number of organisms of a given species (Morris et al 2014, Smith & Grassle 1977).

Table 6. Quadrat location and vegetation types

Quadrat ID	Ecohydrological zone	Vegetation association	Marker coordinates	Orientation
Q1	Swamp Plain	Dry riparian fern scrub (RFS120-B)	143.6942694°E 38.4233453°S	North-west
Q2	Main channel	High-diversity Swampy Riparian Woodland (SRW83-A)	143.6935421°E 38.4224026°S	North-west
Q3	Damp Woodlands	Modified, closed Damp Sands Herb-rich Woodland (DSHW3-B)	143.6992889°E 38.4217217°S	North-east
Q4	Swamp Plain	High-diversity riparian fern scrub (RFS120-A)	143.6971363°E 38.4214326°S	North-west
Q5	Lowland forest	Lowland Forest (LF16-A1)	143.6987042°E 38.4223024°S	South-east

Table 7. Braun-Blanquet scale

Score	Cover range	Abundance value
+	<1% Very few individuals	0.1
1	1-5% Many individuals	2.5
2	5-25%	15
3	25-50%	37.5
4	50-75%	62.5
5	75-100%	87.5

3.3 Climate Data

The long-term average annual rainfall for Colac is 727 mm. Both the 2019 and 2020 survey were conducted within years of below average rainfall, whilst the recent surveys saw annual rainfall being higher than the average. Contrastingly to the previous surveys, rainfall was more evenly spread out across the year, rather than any one season contributing a significant proportion of the overall annual rainfall. Climate statistics are given in Table 8 below.

Table 8. Monthly rainfall prior to the 2019, 2020 and 2022 surveys (BOM 2023)

Month	Rainfall (mm)		
	2019	2020	2022*
Rainfall total for 3 months prior to survey (mm)	286.4	277	314.5
Rainfall total for 12 months prior to survey (mm)	509.5	650	806.9

**note – as the 2022 surveys spanned across several months, as such November was the chosen month for this data*

4. Results

4.1 Vegetation transects

4.1.1 Swamp Plain

Transects 1, 2, 3, and 4 traverse the boundary between tree-dominated woodlands and the scrub-dominated swamp plain. Results from 2020 for all transects show that there are a variety of dominances of vegetation type across the different transects.

Transect 1 has been consistently dominated by Riparian Fern Scrub despite fluctuations in species composition over the monitoring period, which can be attributed to changes in species associated with Wet Verge Sedgeland (Figure 2). Notably, species primarily associated with Swampy Riparian Woodland have become more prevalent at this site and potentially indicates the beginning of a shift in the community towards a tree-dominated ecosystem.

Transect 2 has remained largely unchanged over the course of the monitoring period, showing a strong association with Riparian Fern Scrub which has not changed significantly (Figure 3). Changes in the small woodland component of this site tend to indicate fluctuations between Swampy Riparian Woodland and Damp Sands Herb-rich Woodland rather than a trend away from a scrub dominated system.

Transect 3 has seen an increase in the abundance of Damp-sands Herb-rich Woodland across the duration of the three monitoring seasons (Figure 4). This can be attributed to the recovery of vegetation post-fire, with areas previously without vegetation cover (i.e. bareground/litter/logs) slowly disappearing. The small decrease in Riparian Fern Scrub may also indicate a broader trend towards a more woodland dominated community in this part of the swamp.

Transect 4 showed a very similar trend as Transect 3, with the exception that the increasing abundance in Damp-sands Herb-rich Woodland appears to be driven by a shift away from Riparian Fern-scrub rather than post-fire recovery (Figure 5).

Overall, the results of the transect analysis in the swamp plain show that post-fire recovery continues however in some parts of the swamp, this includes a shift in vegetation composition towards woodland dominated ecosystems.

Figure 2. Transect 1 vegetation type dominance across the 2019, 2020 and 2022 monitoring periods

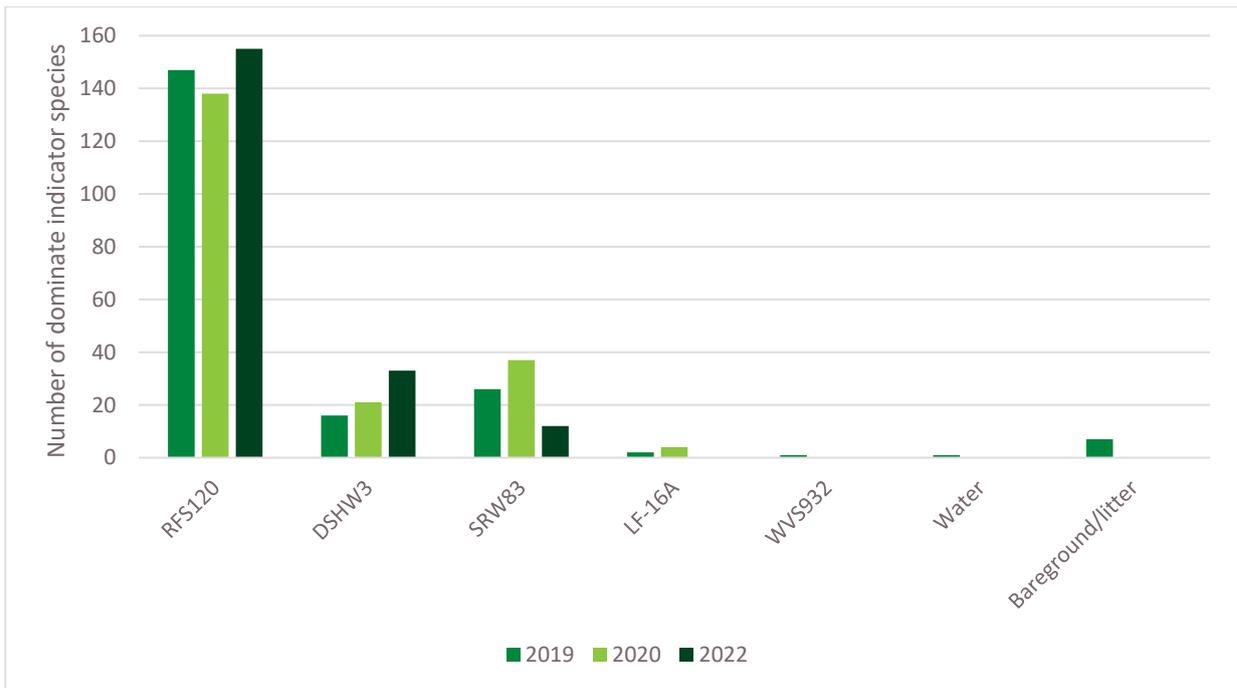

Figure 3. Transect 2 vegetation type dominance across the 2019, 2020 and 2022 monitoring periods

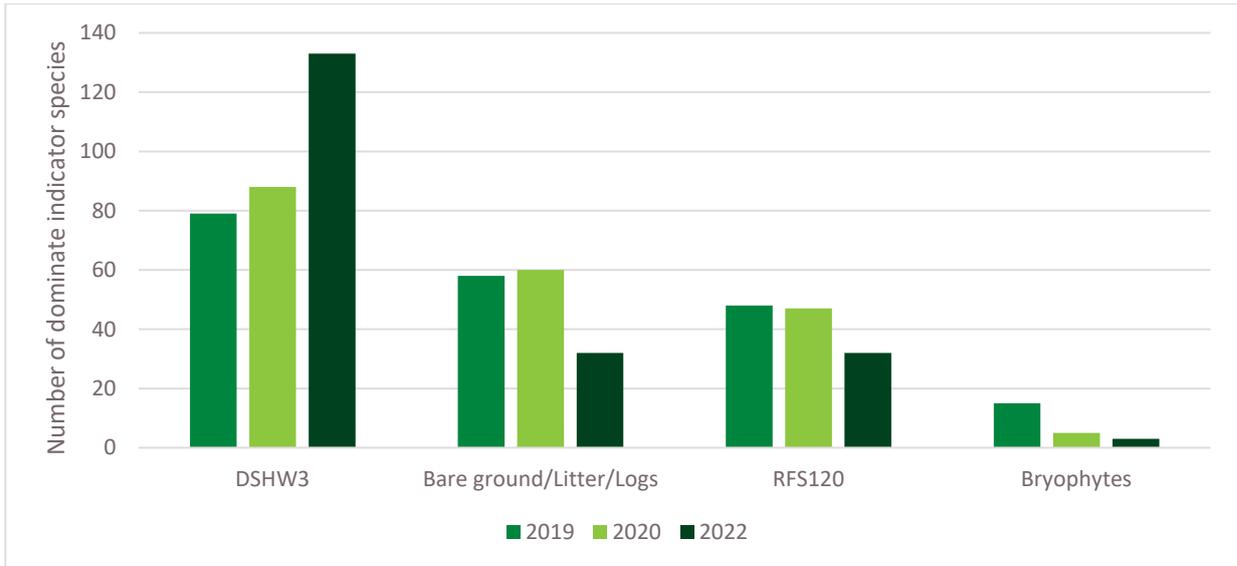

Figure 4. Transect 3 vegetation type dominance across the 2019, 2020 and 2022 monitoring periods

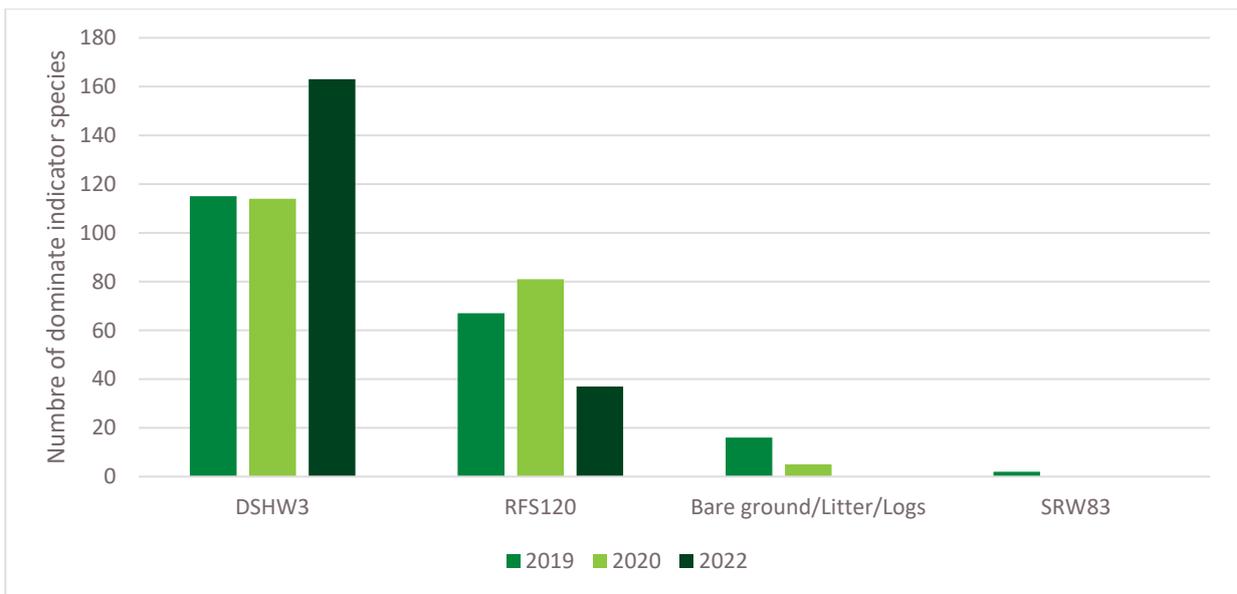

Figure 5. Transect 4 vegetation type dominance across the 2019, 2020 and 2022 monitoring periods

4.1.2 Woodlands

Transect 6, which is located approximately 20-80m to the south-east of the swamp plain, was installed in 2020 to monitor the transitional zone between the Lowland Forest and Damp Sands Herb-rich Woodland communities (Figure 6).

The results from this transect continue to indicate that damp woodlands is the dominant community however, the 2022 results also indicate a reduction in the number of damp woodlands species compared to the 2019 results. This reduction coincided with an increase in the number of lowland forest species and a decrease in the proportional area without vegetation cover.

Whilst data is insufficient to draw substantial conclusions, the analysis suggests a potential shift in the composition of this site towards Lowland Forest.

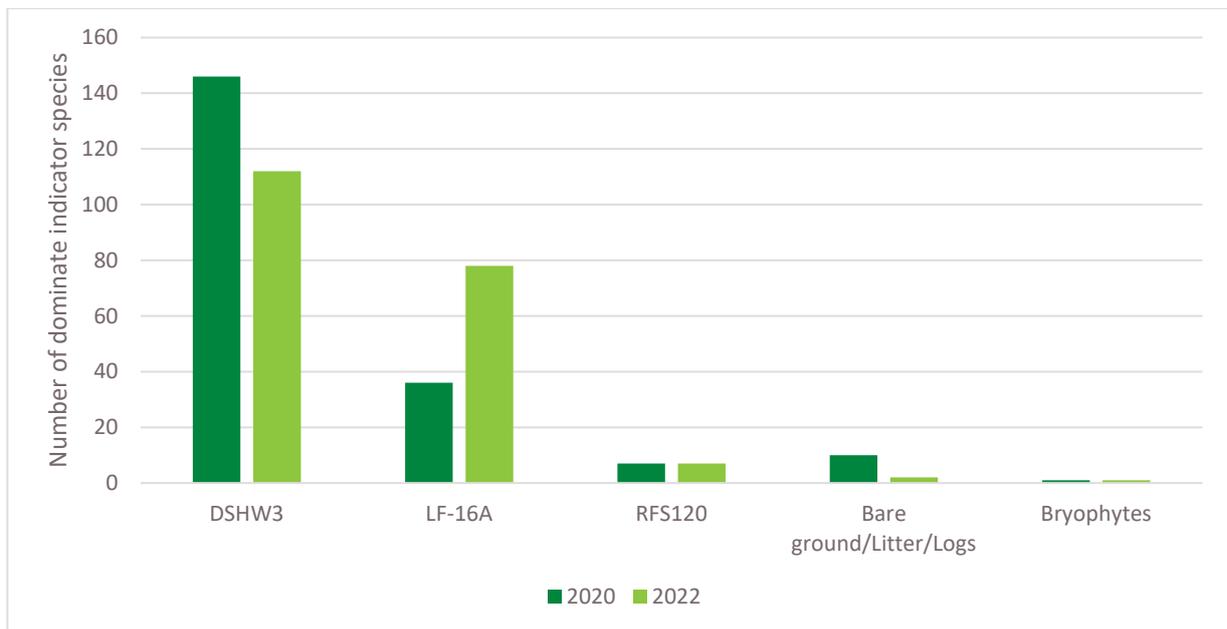

Figure 6. Transect 6 vegetation type dominance across the 2020 and 2022 monitoring periods

4.1.3 Main Channel

Transects 5, 7 and 8 intersect the main channel and adjacent swamp plain and woodland vegetation.

Results from transect 5 have remained similar across the entirety of the survey period (Figure 7). Water dominates this transect as the end extends into the large pond at the east of the swamp. No particular vegetation community dominated beyond the edge of the water, with all represented in part in the floristic diversity of the site.

Transect 7 has remained largely consistent across the two years it has been surveyed (Figure 8), being dominated by Riparian Fern Scrub, which increased whilst Swampy Riparian Woodland has declined. Whilst data is insufficient to draw substantial conclusions, the change observed may suggest a slow shift away from woodland communities to wetter scrub dominated communities is occurring at this location.

Transect 8 saw an increase in the overall abundance of Damp Sands Herb-rich Woodland and a sharp decline in Swampy Riparian Woodland (Figure 9). Based on the limited results, the change observed may suggest a slow shift towards drier woodland communities at this location.

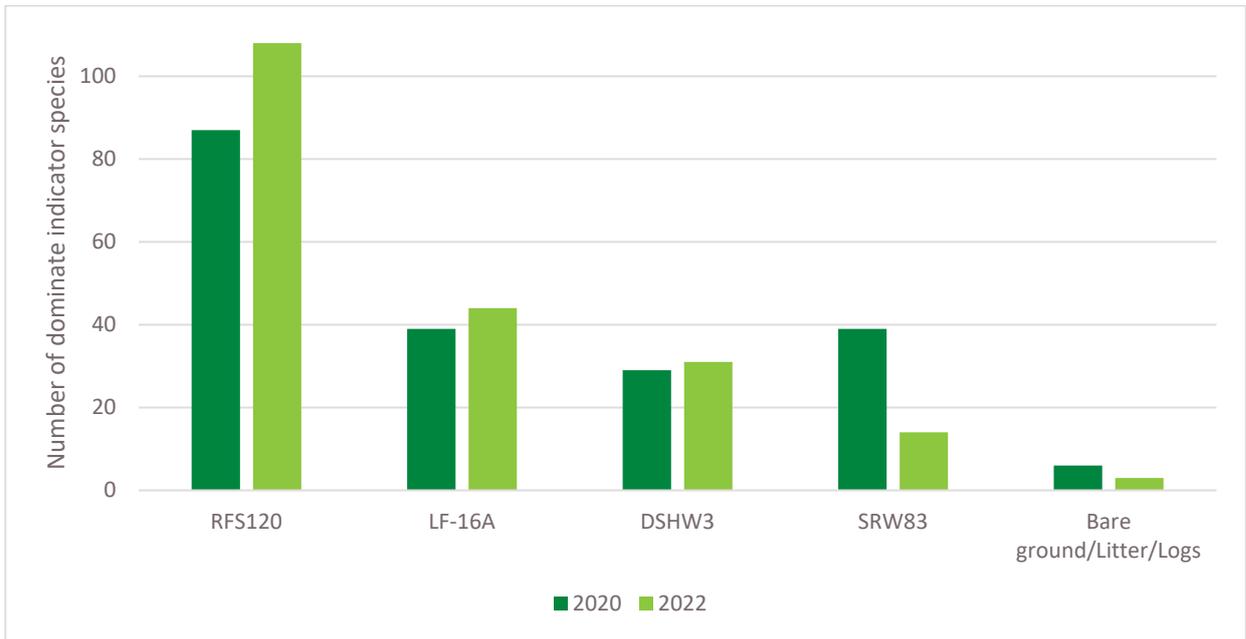

Figure 8: Transect 7 vegetation type dominance across the 2020 and 2022 monitoring periods

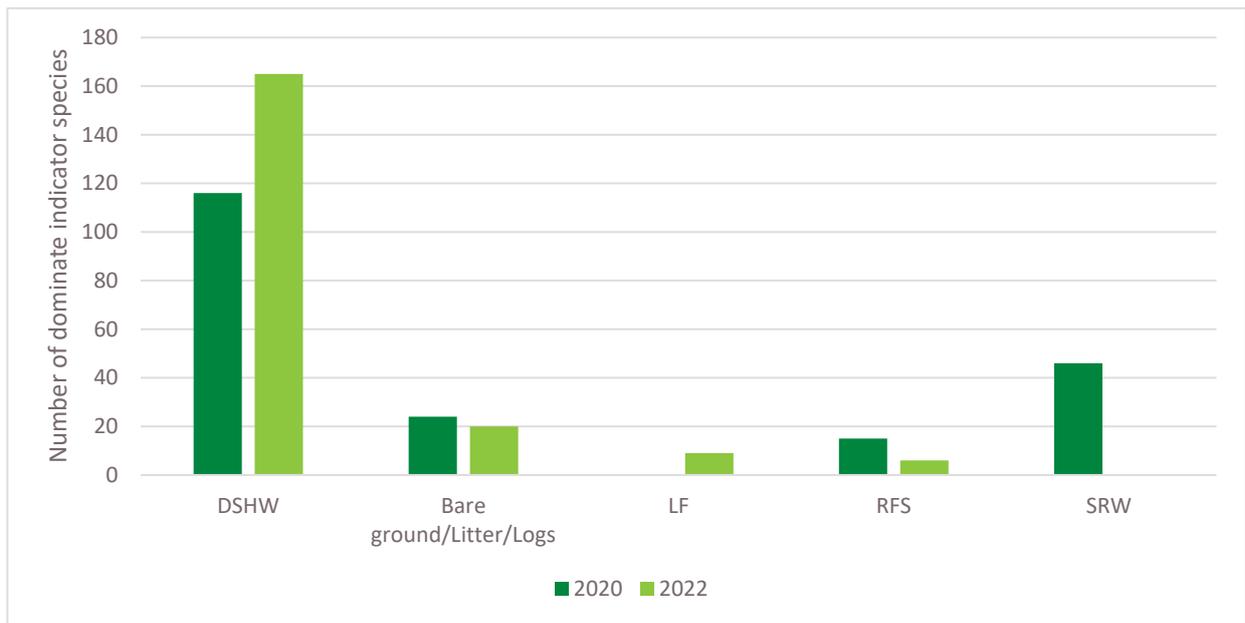

Figure 9: Transect 8 vegetation type dominance across the 2020 and 2022 monitoring periods

4.2 Floristic quadrats

4.2.1 Floristic diversity

Fluctuations in flora species diversity have been observed across the survey period (Figure 10), with quadrats 1, 3 and 5 reporting a reduction in the number of flora species and quadrats 2 and 4 reporting an increase in the number of flora species compared to the 2020 results. It is noted that differences recorded in quadrat 5 may also be attributable to slight differences in the monitoring location given the initial monitoring point could not be relocated. Changes in species diversity could also be attributed to natural seasonal variation or the influx of water following a wet winter period.

4.2.2 Structural diversity

Similar to species diversity, there has been a fluctuation in structural diversity observed across the survey period (Figure 11), with decreased observed in quadrats 1, 3 and 5 and increases observed in quadrats 2 and 4. It is noted that differences recorded in quadrat 5 may also be attributable to slight differences in the monitoring location given the initial monitoring point could not be located.

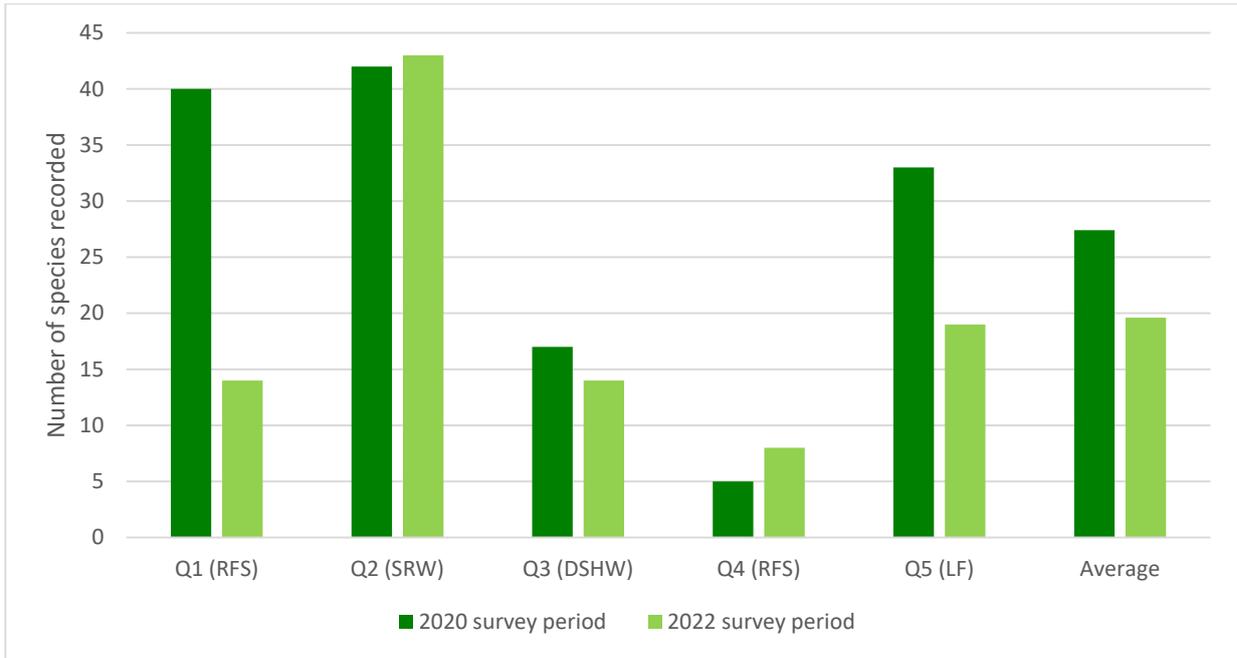

Figure 10. Floristic diversity across the five quadrat plots

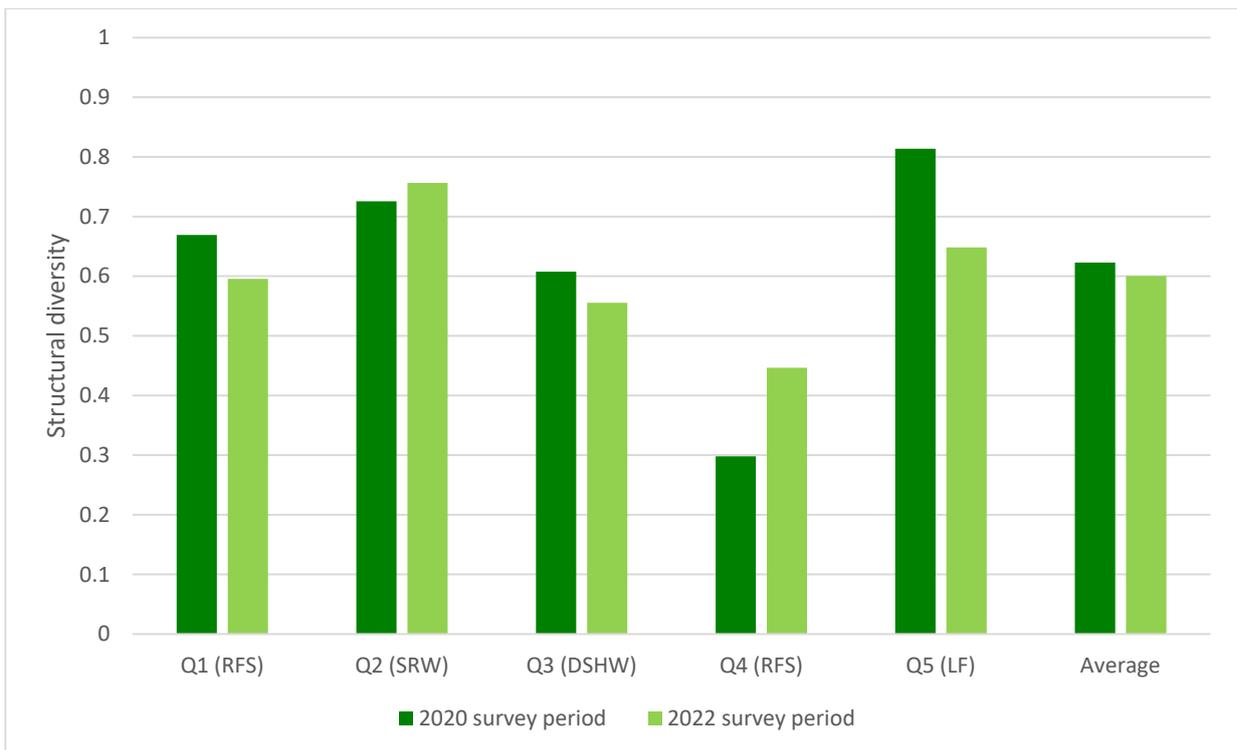

Figure 11. Structural diversity across the five quadrat plots

5. Discussion

The following provides a discussion of the findings of the 2022 vegetation monitoring assessment considering the ‘improve the ecological values of Big Swamp’ objective as set out in the REPP.

Whilst the following discussion is primarily based on the monitoring period (i.e. 2019 – 2023), it must be recognised that the swamp has seen substantial recovery of vegetation since remediation began post drought and fires (circa 2012). Whilst data is limited, a transect completed by Jacobs (2015) recorded only four native species along a similar alignment to Transect 3, which based on 2023 data now has 11 different native species (Appendix D).

5.1 Vegetation communities

Results indicate that whilst recovery in the swamp continues, the extent and composition of vegetation continues to change post-fires. Several of the transects (namely T1 and T4) indicate a continuing shift to woodland dominated communities within the swamp plain. This is unsurprising given the significant disturbance that has occurred (e.g. drought, fires and subsequent erosion) which has altered the surface and sub-surface hydrology in the swamp and lead to some areas becoming wetter and others drier. A continuing trend towards woodlands and away from scrubs is likely to continue for several decades as the ecosystem adjusts to the changes in the base environment.

This does not necessarily indicate that ecological values are not improving in the swamp, but rather the ecosystem as a whole is adapting to the new environmental conditions and hydrological regimes post-fires. This ‘rebalancing’ of the system is likely to take many decades and it is reasonable to expect that, provided further severe drying and any associated disturbance is minimised, this process will see an improvement in the ecological values of the swamp as vegetation communities mature and stabilise.

5.2 Floristic diversity

Overall, the swamp experienced a minor decline in floristic diversity compared to the 2020 results. The most notable decline is associated with the western end of the swamp, and can potentially be attributed to the extensive flooding present for extended periods over the past several years. A shift in the species composition away from a diverse grass and herb rich understorey to one dominated by sedges was observed in the field and can be seen in the data (Appendix E). The potential reason for the decline associated with quadrat 5 (in lowland forest outside the swamp’s extent) may be associated with the difficulties in relocating the quadrat and should be reviewed carefully in future monitoring reports.

Elsewhere floristic diversity has increased, albeit marginally. Of note is the improvement seen in the centre of the swamp and which had some of the highest levels of disturbance due to fires, subsidence and erosion. Whilst minimal, the improvement indicates species are recolonising the swamp plain and suggests a positive trend towards recovery.

Further monitoring data is required to better constrain potential natural fluctuations from long-term trends.

5.3 Structural diversity

Overall, the monitoring data indicates that there has not been a significant change in structural diversity within the swamp since 2020. Of note, quadrat 4 in the centre of the swamp has shown a marked improvement in structure and, like the improvement in floristic diversity in this location, indicates the community is still recolonising this site and vegetation structure maturing.

The decline in structural diversity in quadrat 5 aligns with the change in floristic diversity and is surprising within a community type that did not experience significant disturbance, as the rest of the swamp did, and is relatively mature and stable. Given the marker post for this quadrat had been removed/was unable to be located, the change likely represents issues with sampling due to the quadrat being located.

Further monitoring data is required to better constrain potential natural fluctuations from long-term trends.

6. Conclusion

6.1 REPP objective

When considering the REPP's objective to 'improve the ecological values of Big Swamp', the monitoring data indicates a significant improvement has not yet occurred since 2019. This is unsurprising given that monitoring is still in the early stages and conditions in the swamp continue to fluctuate from year to year. Whilst a decline in floristic diversity has been recorded in some locations, a significant decline in the floristic or structural diversity across the entirety of the swamp cannot be seen, and the sites most impacted by past disturbance are showing improvements (e.g. quadrat 4 in the centre of the swamp).

It should also be recognised that the swamp has seen a significant recovery in the cover and structure of vegetation post drought and fires (circa. 2012), with a previous transect recorded in 2015 showing less than half the floristic diversity now being recorded at the same location. In this context, the swamp has shown an improvement in the ecological values and ongoing monitoring since 2019 should be used to provide an indication of how this post-fire recovery continues towards a mature, resilient and diverse ecosystem in coming years.

Encroachment of woodland communities, which may not have been predominantly associated with the swamp prior to impacts, should continue to be monitored. Whilst there is not currently a risk of existing communities disappearing from the swamp entirely, those predominantly associated with the swamp plain (i.e. riparian fern scrub) appear to be reducing in extent. If this trend were to continue, it may constitute a decline in the 'ecological values' of the swamp in the long-term.

Further monitoring over coming years will provide better insight into long-term changes within the swamp.

6.2 Development of success criteria

Subsequent review of the factors which lead to degradation of the swamp from the late 1990s to early 2010s, including those outside of Barwon Waters control such as droughts and modification of surface flows upstream and downstream of Big Swamp, have prompted further review of the interim success criteria. In particular, remediation is not intended to return the swamp to pre-drought conditions, recognising the significant changes that have occurred and the need to facilitate the swamps natural recovery to ensure the establishment of a functional, resilient ecosystem.

Taking into consideration the results of monitoring to date, and previous studies, the final success criteria should take into account:

- Changes in the understanding of the factors which have resulted in impacts to the swamp, including irreversible changes within the catchment (such as land clearing and modification of waterways).
- The fundamental changes to the swamp's environment that occurred between late 1990s and early 2010s, including drying of the swamp, fires, loss of organic biomass and altered soil structure, and erosion of the swamp plain and subsequent changes in surface/sub-surface hydrology.

- The issues associated with using pre-drought conditions as a baseline for success. Success criteria based on post-fire conditions in the swamp as the baseline provide a more realistic measure of ecosystem recovery and improvement in values.
- Realistic timeframes linked to the vision and objectives of the remediation plan.
